

DuckieBot Follower

António Ribeiro up201906761@edu.fe.up.pt Filipe Campos up201905609@edu.fe.up.pt Francisco Cerqueira up201905337@edu.fe.up.pt

Lane Following

Use standard CV algorithms to move along the road lane

ArUco

Use ArUco markers to find the guidebot's distance and orientation

Object Detection

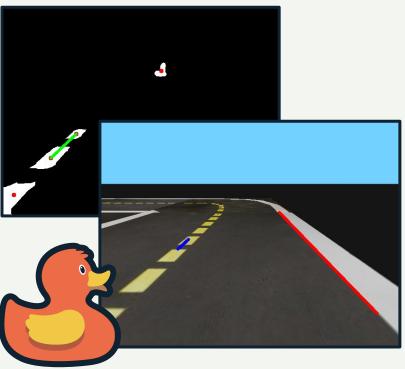

Train and use a object detection DNN model to retrieve the guidebot's pose

Lane following

- Tracks the yellow, white and red lane markings.
- Uses OpenCV algorithms for line detection: color masks, erosion/dilation, Hough transform.
- Computes a yellow line interpolation.
- Determines the line angles and adjusts speed accordingly.
- Uses event driven movement and simple loops for intersection paths.

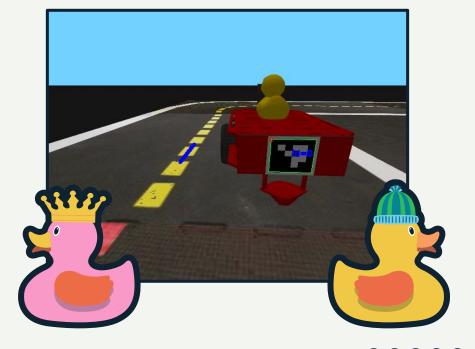

ArUco Marker Detection

- OpenCV ArUco module.
- 4×4 marker.
- Corner detection used to retrieve:
 - Rotation (rvecs).
 - Translation (tvecs).
- Vectors used to estimate guide's pose:
 - o Distance.
 - Relative Angle.

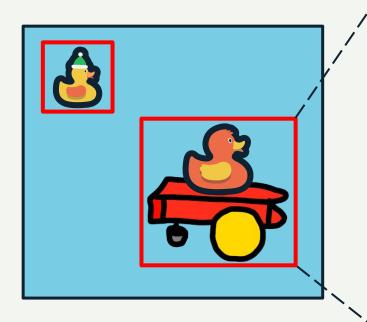

Object Detection

Each prediction contains 17 output values:

- Objectness (1)
- Bounding Box Regression (4, xywh)
- Class Classification (2, Duckiebot or Duckie)
- Distance Ordinal Regression (5, VC/C/M/F/VF)
- Rotation Ordinal Regression (5, VL/L/M/R/VR)

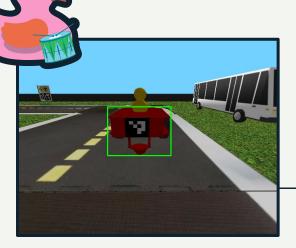

Dataset Collection

Label:

Class: BB:

Rel. Position: Rel Orient.: 1 220 164 157 121 0.3533 0.0 -0.0133 -0.00552 Methodology

Capture screenshots throughout various simulations.

Results

- The lane following implementation is a limitation, tending towards becoming unstable due to accumulating errors over longer runs.
- ArUco detection offers better results upon starting the simulation, but decays over time.
- The camera view has limited visibility in sharp turns, which hinders the ability to detect the guide robot.

Conclusions and Future Work

Lane Following

Implement a RL or PID-based controller for movement

Dataset

Gather new screenshots from the simulation

Object Detection

Use other approaches to train the models

Thank you!
